Entering and cleaning data #3

Group project

Project

Everyone will be working on some aspect of the same large project.

This year, the project is based on data on drugs under consideration for treatment of tuberculosis. The data is from a research group here at CSU.

Overall, the class will create a Shiny web app based on R code. The research group would like for this to be able to input files in the format they use, provide some useful summaries of relationships among the measured characteristics of each drug, and provide useful visualizations.

The class will be divided into 3-4 groups to work on specific parts of this project.

Project

Each candidate drug has a number of measured characteristics (independent variables). These include chemical and biological characteristics that might help to explain how effective the drugs are. Some of these characteristics might be strongly correlated with each other.

For each drug, there are also several replicated measures of how effective the drug is against tuberculosis (**dependent variable**). Ultimately, we'd like to have an idea of which drugs are most effective and which drug characteristics are associated with effectiveness.

Project

The data starts out in a somewhat messy spreadsheet format. A critical step will be developing code to input and "tidy" this data. The research group plans to continue collecting similar data in the future (possibly on different drugs), so they need a way to input and clean the data. The research group will also want a way to download any summary tables and figures that are generated by the code.

Finally, we'll need to design a framework for the full web application, to make sure that all these pieces come together in an attractive and user-friendly way.

Groups

- Input / output: Create code to read the data in from an Excel sheet and "tidy" the data. There are different Excel sheets for different elements of the measurements, so joining will be required as well. This group will also be in charge of designing the "Input" and "Output" elements of the Shiny web app, so the group can input new datasets and save figures and tables created by the app.
- 2. Associations among independent variables: Create summaries and visualizations of how the independent variables are associated with each other. Here, many of the characteristics of the drugs might be associated with each other, and the drugs might "cluster" into groups based on these characteristics. This group will need to come up with ways (and code) to analyze that in the data. This might include correlation plots, hierarchical cluster analysis, and principal components analysis.

Groups

- 3. Association between dependent and independent variables:
 - Create summaries and visualizations of how the dependent variable is associated with different independent variables. Here, we will try to discover if there are characteristics of the drugs that are associated with effectiveness against TB. This group will need to come up with ways (and code) to analyze that in the data. This might include generalized linear models, scatterplots, and possibly other supervised learning methods.
- 4. **Overall design of Shiny App**: Create the overall framework for the Shiny app, including how to arrange different functionality across different windows and ensuring that the app is aesthetically attractive and easy to use. This group's tasks will be design-heavy, and will likely require the most new mastery of Shiny-specific code.

"Products"

Each group will need to generate:

- 1. The code for their piece of the project (we'll use GitHub to collaborate).
- 2. A brief report (4 to 5 pages) describing how the group tackled their problem, what pieces were particularly challenging and how they tackled those, what they would do differently if they started fresh, and what interesting things they found in this set of data. Each group must submit a draft of this the last Wednesday of class and submit the final version on the day of presentations.
- 3. A presentation (12 minutes maximum) that covers the same material as the report. The groups will present these during finals week, in the time period scheduled for a final exam for our course.

Cleaning very messy data

One version of Atlantic basin hurricane tracks is available here: http://www.nhc.noaa.gov/data/hurdat/hurdat2-1851-2015-070616.txt. The data is not in a classic delimited format:

```

                                                                                                 56.5W, 60, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -999, -
```

This data is formatted in the following way:

- Data for many storms are included in one file.
- Data for a storm starts with a shorter line, with values for the storm ID, name, and number of observations for the storm. These values are comma separated.
- Observations for each storm are longer lines. There are multiple observations for each storm, where each observation gives values like the location and maximum winds for the storm at that time.

Strategy for reading in very messy data:

- 1. Read in all lines individually.
- 2. Use regular expressions to split each line into the elements you'd like to use to fill columns.
- Write functions, loops, or apply calls to process lines and use the contents to fill a data frame.
- 4. Once you have the data in a data frame, do any remaining cleaning to create a data frame that is easy to use to answer research questions.

Because the data is not nicely formatted, you can't use read_csv or similar functions to read it in.

However, the readLines function allows you to read a text file in one line at a time. You can then write code and functions to parse the file one line at a time, to turn it into a dataframe you can use.

The read_lines function from readr will read in lines from a text file directly, without trying to separate into columns. You can use the n_max argument to specify the number of lines to read it.

For example, to read in three lines from the hurricane tracking data, you can run:

```
## [1] "AL011851, UNNAMED, 14,"

## [2] "18510625, 0000, , HU, 28.0N, 94.8W, 80, -999, -999, -

## [3] "18510625, 0600, , HU, 28.0N, 95.4W, 80, -999, -999, -
```

The data has been read in as a vector, rather than a dataframe:

```
class(hurr_tracks)
## [1] "character"
length(hurr_tracks)
## [1] 3
hurr tracks[1]
## [1] "AL011851,
                              UNNAMED,
                                           14,"
```

You can use regular expressions to break each line up. For example, you can use str_split from the stringr package to break the first line of the hurricane track data into its three separate components:

```
library(stringr)
str_split(hurr_tracks[1], pattern = ",")

## [[1]]
## [1] "AL011851" " UNNAMED" " 14"
## [4] ""
```

You can use this to create a list where each element of the list has the split-up version of a line of the original data. First, read in all of the data:

```
## [1] 51521
```

Next, use map with str_split to split each line of the data at the commas:

```
library(purrr)
hurr tracks <- map(hurr tracks, str split,
                 pattern = ",", simplify = TRUE)
hurr_tracks[[1]]
## [,1] [,2]
                                      [,3] [,4]
                              UNNAMED" " 14" ""
## [1,] "AL011851" "
hurr_tracks[[2]][1:2]
## [1] "18510625" " 0000"
```

Next, you want to split this list into two lists, one with the shorter "meta-data" lines and one with the longer "observation" lines. You can use map_int to create a vector with the length of each line. You will later use this to identify which lines are short or long.

```
hurr_lengths <- map_int(hurr_tracks, length)
hurr_lengths[1:17]</pre>
```

```
unique(hurr_lengths)
```

```
## [1] 4 21
```

You can use bracket indexing to split the hurr_tracks into two lists: one with the shorter lines that start each observation (hurr_meta) and one with the storm observations (hurr_obs). Use bracket indexing with the hurr_lengths vector you just created to make that split.

```
hurr_meta <- hurr_tracks[hurr_lengths == 4]
hurr_obs <- hurr_tracks[hurr_lengths == 21]</pre>
```

```
hurr_meta[1:3]
## [[1]]
## [,1] [,2]
                                 [,3] [,4]
## [1,] "AL011851" "
                          UNNAMED" " 14" ""
##
## [[2]]
## [,1] [,2]
                                 [,3] [,4]
## [1,] "AL021851" "
                          UNNAMED" "
##
## [[3]]
## [,1] [,2]
                                  [,3]
                                          [, 4]
                          UNNAMED" "
                                       1" ""
## [1,] "ALO31851" "
```

```
hurr_obs[1:2]
## [[1]]
       [,1]
##
                [,2] [,3] [,4] [,5] [,6]
## [1,] "18510625" " 0000" " " " HU" " 28.0N" " 94.8W" " 80"
       [,9]
             [,10] [,11] [,12] [,13] [,14]
##
                                                 [,15]
  [1,] " -999" " -999" " -999" " -999" " -999" " -999" " -999"
       [,17] [,18] [,19] [,20] [,21]
##
## [1,] " -999" " -999" " -999" " -999" ""
##
## [[2]]
       [,1] [,2] [,3] [,4] [,5] [,6]
##
  [1,] "18510625" " 0600" " " " HU" " 28.0N" " 95.4W" " 80"
             [,10] [,11] [,12] [,13] [,14]
##
       [,9]
                                                 [.15]
       " -999" " -999" " -999" " -999" " -999" " -999"
       [,17] [,18] [,19] [,20] [,21]
##
                                                      22
## [1.] " -999" " -999" " -999" " -999" ""
```

Now, you can use bind_rows from dplyr to change the list of metadata into a dataframe. (You first need to use as_tibble with map to convert all elements of the list from matrices to dataframes.)

```
library(dplyr); library(tibble)
hurr_meta <- hurr_meta %>%
  map(as_tibble) %>%
  bind_rows()
hurr_meta %>% slice(1:3)
```

```
## # A tibble: 3 x 4
##
           V1
                                 V2
                                         V3
                                                V4
##
        <chr>
                              <chr> <chr> <chr> <chr>
## 1 AL011851
                           UNNAMED
                                          14
## 2 ALO21851
                           UNNAMED
## 3 AT.031851
                            UNNAMED
```

You can clean up the data a bit more.

First, the fourth column doesn't have any non-missing values, so you can get rid of it:

```
unique(hurr_meta$V4)
## [1] ""
```

Second, the second and third columns include a lot of leading whitespace:

```
hurr_meta$V2[1:2]

## [1] " UNNAMED" " UNNAMED"
```

• Last, we want to name the columns.

```
hurr meta <- hurr meta %>%
 select(-V4) %>%
 rename(storm id = V1, storm name = V2, n obs = V3) %>%
 mutate(storm name = str trim(storm name),
        n obs = as.numeric(n obs))
hurr meta %>% slice(1:3)
## # A tibble: 3 x 3
##
    storm id storm name n obs
##
       <chr> <chr> <chr> <dbl>
## 1 ALO11851
               UNNAMED
                          14
## 2 AL021851
                UNNAMED
## 3 AL031851
               UNNAMED
```

[1] 49691

Now you can do the same idea with the hurricane observations. First, we'll want to add storm identifiers to that data. The "meta" data includes storm ids and the number of observations per storm. We can take advantage of that to make a storm_id vector that will line up with the storm observations.

```
storm_id <- rep(hurr_meta$storm_id, times = hurr_meta$n_obs)
head(storm_id, 3)

## [1] "AL011851" "AL011851"
length(storm_id)

## [1] 49691
length(hurr_obs)</pre>
```

26

```
hurr_obs <- hurr_obs %>%
 map(as_tibble) %>%
 bind rows() %>%
 mutate(storm id = storm id)
hurr_obs %>% select(V1:V2, V5:V6, storm_id) %>% slice(1:3)
## # A tibble: 3 x 5
##
          V1
               V2
                    V5
                              V6 storm id
##
       <chr> <chr> <chr> <chr>
                                    <chr>
## 1 18510625 0000 28.0N 94.8W AL011851
## 2 18510625 0600 28.0N 95.4W AL011851
## 3 18510625 1200 28.0N
                          96.0W AL011851
```

To finish, you just need to clean up the data. Now that the data is in a dataframe, this process is inline with what you've been doing with dplyr and related packages.

The "README" file for the hurricane tracking data is useful at this point:

http:

//www.nhc.noaa.gov/data/hurdat/hurdat2-format-atlantic.pdf

First, say you only want some of the columns for a study you are doing. You can use select to clean up the dataframe by limiting it to columns you need.

If you only need date, time, storm status, location (latitude and longitude), maximum sustained winds, and minimum pressure, then you can run:

```
## # A tibble: 3 x 5
## date time status latitude longitude
## <chr> <chr> <chr> <chr> +# 1 18510625 0000 HU 28.0N 94.8W
```

Next, the first two columns give the date and time. You can unite these and then convert them to a Date-time class.

```
library(tidyr); library(lubridate)
hurr_obs <- hurr_obs %>%
  unite(date_time, date, time) %>%
  mutate(date_time = ymd_hm(date_time))
hurr_obs %>% slice(1:3) %>%
  select(date_time, status, latitude, longitude)
```

```
## # A tibble: 3 \times 4
##
              date_time status latitude longitude
##
                 \langle dt.t.m \rangle
                         <chr>
                                  <chr>
                                            <chr>>
## 1 1851-06-25 00:00:00
                            HU
                                  28.0N
                                            94.8W
## 2 1851-06-25 06:00:00
                            HU
                                  28.0N
                                            95.4W
## 3 1851-06-25 12:00:00 HU
                                  28.0N
                                            96.0W
```

Next, you can create a status_long factor with more meaningful names:

```
unique(hurr_obs$status)
## [1] " HU" " TS" " EX" " TD" " LO" " DB" " SD" " SS" " WV"
storm_severity <- tribble(
  ~ status, ~status_long,
  "TD", "Tropical depression",
  "TS", "Tropical storm",
  "HU", "Hurricane",
  "EX", "Extratropical cyclone",
  "SD", "Subtropical depression",
  "SS", "Subtropical storm",
  "LO", "Other low",
  "WV", "Tropical wave",
  "DB", "Disturbance"
```

##

hurr_obs <- hurr_obs %>%

Next, you can create a status_long factor with more meaningful names:

```
mutate(status = str_trim(status)) %>%
  left_join(storm_severity, by = "status") %>%
  mutate(status_long = factor(status_long))
hurr_obs %>% slice(1:2) %>% select(date_time, status, status_long
## # A tibble: 2 x 3
## date_time status status_long
```

<fctr>

<dttm> <chr>

1 1851-06-25 00:00:00 HU Hurricane ## 2 1851-06-25 06:00:00 HU Hurricane

Now, you can clean up the latitude and longitude. Ultimately, we'll want numeric values for those so we can use them for mapping. You can use regular expressions to separate the numeric and non-numeric parts of these columns. For example:

```
head(str_extract(hurr_obs$latitude, "[A-Z]"))
## [1] "N" "N" "N" "N" "N"
head(str_extract(hurr_obs$latitude, "[^A-Z]+"))
## [1] " 28.0" " 28.0" " 28.0" " 28.1" " 28.2" " 28.2"
```

Use this idea to split the numeric latitude from the direction of that latitude:

Now these elements are in separate columns:

```
hurr obs %>%
 select(latitude, lat dir, longitude, lon dir) %>%
 slice(1:2)
## # A tibble: 2 x 4
##
    latitude lat_dir longitude lon_dir
##
      <dbl> <chr> <dbl> <chr>
## 1
         28
                N 94.8
## 2 28
            N 95.4 W
unique(hurr_obs$lat_dir)
## [1] "N"
unique(hurr_obs$lon dir)
```

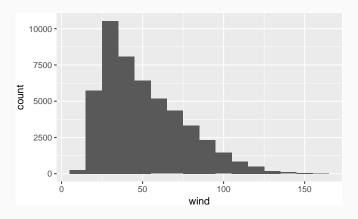

If we're looking at US impacts, we probably only need observations from the western hemisphere, so let's filter out other values:

```
hurr_obs <- hurr_obs %>%
filter(lon_dir == "W")
```

Next, clean up the wind column:

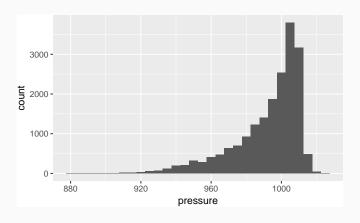

Check the cleaned measurements:

```
library(ggplot2)
ggplot(hurr_obs, aes(x = wind)) +
  geom_histogram(binwidth = 10)
```

Clean and check air pressure measurements in the same way:

```
ggplot(hurr_obs, aes(x = pressure)) +
  geom_histogram(binwidth = 5)
```

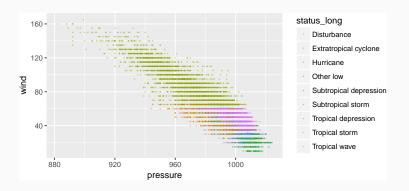

Check some of the very low pressure measurements:

```
hurr_obs %>% arrange(pressure) %>%
select(date_time, wind, pressure) %>% slice(1:5)
```

```
## # A tibble: 5 \times 3
##
              date_time wind pressure
##
                 <dttm> <dbl>
                                <dbl>
## 1 2005-10-19 12:00:00
                         160
                                  882
## 2 1988-09-14 00:00:00 160
                                 888
## 3 1988-09-14 06:00:00 155
                                 889
## 4 1935-09-03 00:00:00 160
                                 892
## 5 1935-09-03 02:00:00
                        160
                                  892
```

Explore pressure versus wind speed, by storm status:

Next, we want to map storms by decade. Add hurricane decade:

```
## [1] "1850s" "1860s" "1870s" "1880s" "1890s" "1900s" "1910s"
## [9] "1930s" "1940s" "1950s" "1960s" "1970s" "1980s" "1990s"
## [17] "2010s"
```

Add logical for whether the storm was ever category 5:

```
hurr_obs <- hurr_obs %>%
  group_by(storm_id) %>%
  mutate(cat_5 = max(wind) >= 137) %>%
  ungroup()
```

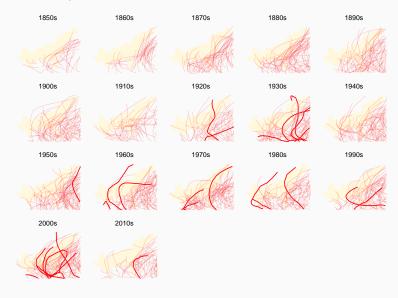

To map the hurricane tracks, you need a base map to add the tracks to. Pull data to map hurricane-prone states:

```
east states <- c("florida", "georgia", "south carolina",
                 "north carolina", "virginia", "maryland",
                 "delaware", "new jersey", "new york",
                 "connecticut", "massachusetts",
                 "rhode island", "vermont", "new hampshire",
                 "maine", "pennsylvania", "west virginia",
                 "tennessee", "kentucky", "alabama",
                 "arkansas", "texas", "mississippi",
                 "louisiana")
east_us <- map_data("state", region = east_states)</pre>
```

Plot tracks over a map of hurricane-prone states. Add thicker lines for storms that were category 5 at least once in their history.

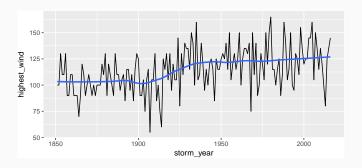

```
ggplot(east us, aes(x = long, y = lat, group = group)) +
  geom_polygon(fill = "cornsilk", color = "cornsilk") +
  theme void() +
  xlim(c(-108, -65)) + ylim(c(23, 48)) +
  geom_path(data = hurr_obs,
            aes(x = -longitude, y = latitude,
                group = storm id),
            color = "red", alpha = 0.2, size = 0.2) +
  geom_path(data = filter(hurr_obs, cat_5),
            aes(x = -longitude, y = latitude,
                group = storm_id),
            color = "red") +
  facet wrap(~ decade)
```

Plot tracks by decade:

Maximum wind observed each year:

```
hurr_obs %>%
  mutate(storm_year = year(date_time)) %>%
  group_by(storm_year) %>%
  summarize(highest_wind = max(wind, na.rm = TRUE)) %>%
  ggplot(aes(x = storm_year, y = highest_wind)) +
  geom_line() + geom_smooth(se = FALSE, span = 0.5)
```

There is an R package named gender that predicts whether a name is male or female based on historical data:

Vignette for gender package

This package uses one of several databases of names (here, we'll use Social Security Administration data), inputs a year or range of years, and outputs whether a name in that year was more likely female or male.

We can apply a function from this package across all the named storms to see how male / female proportions changed over time.

First, install the package (as wll as genderdata, which is required to use the package). Once you do, you can use gender to determine the most common gender associated with a name in a given year or range of years:

```
# install.packages("gender")
# install.packages("genderdata", type = "source",
# repos = "http://packages.ropensci.org")
library(gender)
gender("KATRINA", years = 2005)[ , c("name", "gender")]
```

```
## # A tibble: 1 x 2
## name gender
## <chr> <chr> ## 1 KATRINA female
```

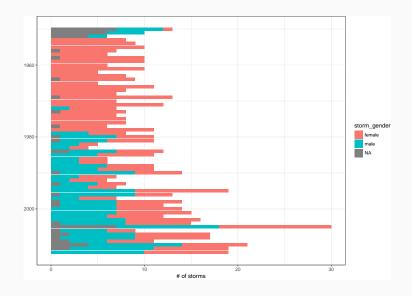

To apply this function across all our storms, it helps if we write a small function that "wraps" the gender function and outputs exactly (and only) what we want, in the format we want:

Now we can use mapply with this wrapper function to apply it across all our named storms:

```
hurr genders <- hurr meta %>%
  filter(storm name != "UNNAMED") %>%
  mutate(storm year = substring(storm id, 5, 8),
         storm year = as.numeric(storm_year)) %>%
  filter(1880 <= storm year & storm year <= 2012) %>%
  select(storm name, storm year, storm id) %>%
  mutate(storm_gender = mapply(get_gender,
                               storm_name = storm_name,
                               storm year =
                                 as.numeric(storm_year)))
```

Now, plot a bar chart with the number of male, female, and unclear storms each year:

```
hurr_genders %>%
  group_by(storm_year, storm_gender) %>%
  summarize(n = n()) %>%
  ggplot(aes(x = storm_year, y = n, fill = storm_gender)) +
  geom_bar(stat = "identity") +
  coord_flip() +
  scale_x_reverse() +
  theme_bw() +
  xlab("") + ylab("# of storms")
```

Next, you can write a function to plot the track for a specific storm. You'll want to be able to call the function by storm name and year, so join in the storm names from the hurr_meta dataset. We'll exclude any "UNNAMED" storms.

```
hurr_obs <- hurr_obs %>%

left_join(hurr_meta, by = "storm_id") %>%

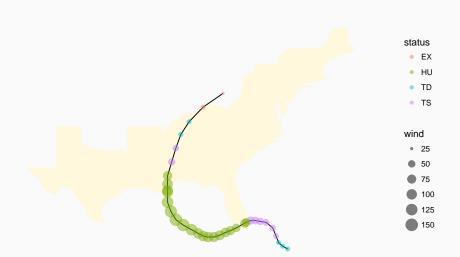

filter(storm_name != "UNNAMED") %>%

mutate(storm_year = year(date_time))
```

Next, write a function to plot the track for a single storm. Use color to show storm status and size to show wind speed.

```
map_track <- function(storm, year, map_data = east_us,</pre>
                      hurr data = hurr obs){
  to_plot <- hurr_obs %>%
    filter(storm_name == toupper(storm) & storm_year == year)
  out <- ggplot(east us, aes(x = long, y = lat,
                             group = group)) +
    geom_polygon(fill = "cornsilk") +
    theme void() +
    xlim(c(-108, -65)) + ylim(c(23, 48)) +
    geom_path(data = to plot,
              aes(x = -longitude, y = latitude,
                  group = NULL)) +
    geom_point(data = to_plot,
              aes(x = -longitude, y = latitude,
                  group = NULL, color = status,
                  size = wind), alpha = 0.5)
  return(out)
```

map_track(storm = "Katrina", year = "2005")

map_track(storm = "Camille", year = "1969")

readLines

You can also write code with readLines that will read, check, and clean each line, one line at a time.

```
con <- file("~/my file.txt", open = "r")</pre>
while (length(single_line <-</pre>
              readLines(con, n = 1,
                         warn = FALSE)) > 0) {
  ## Code to check and clean each line and
  ## then add it to "cleaned" data frame.
  ## Run operations on `single_line`.
  }
close(con)
```

This can be particularly useful if you're cleaning a very big file, especially if there are many lines you don't want to keep.

Pulling online data

APIs

API: "Application Program Interface"

An API provides the rules for software applications to interact. In the case of open data APIs, they provide the rules you need to know to write R code to request and pull data from the organization's web server into your R session.

Often, an API can help you avoid downloading all available data, and instead only download the subset you need.

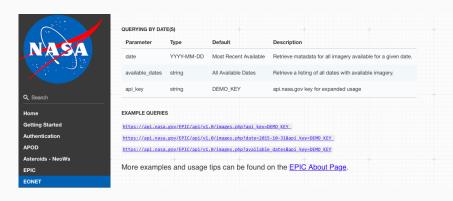

APIs

Strategy for using APIs from R:

- Figure out the API rules for HTTP requests
- Write R code to create a request in the proper format
- Send the request using GET or POST HTTP methods
- Once you get back data from the request, parse it into an easier-to-use format if necessary

API documentation

Start by reading any documentation available for the API. This will often give information on what data is available and how to put together requests.

Source: https://api.nasa.gov/api.html#EONET

API key

Many organizations will require you to get an API key and use this key in each of your API requests. This key allows the organization to control API access, including enforcing rate limits per user. API rate limits restrict how often you can request data (e.g., an hourly limit of 1,000 requests per user for NASA APIs).

You should keep this key private. In particular, make sure you do not include it in code that is posted to GitHub.

The riem package, developed by Maelle Salmon and an ROpenSci package, is an excellent and straightforward example of how you can use R to pull open data through a web API.

This package allows you to pull weather data from airports around the world directly from the lowa Environmental Mesonet.

To get a certain set of weather data from the lowa Environmental Mesonet, you can send an HTTP request specifying a base URL, "https://mesonet.agron.iastate.edu/cgi-bin/request/asos.py/", as well as some parameters describing the subset of dataset you want (e.g., date ranges, weather variables, output format).

Once you know the rules for the names and possible values of these parameters (more on that below), you can submit an HTTP GET request using the GET function from the httr package.

```
• • • < > 
                                           🔯 :gi-bin/request/asos.pv?station=DEN&data=sped&vear1=2016&month1 💍
#DEBUG: Format Typ
                      -> comma
#DEBUG: Time Period
                      -> 2016-01-01 00:00:00+00:00 2016-10-25 00:00:00+00:00

DEN, 2016-01-01 11:53,5.8
DEN.2016-01-01 12:53.6.9
DEN,2016-01-01 13:53,9.2
```

https://mesonet.agron.iastate.edu/cgi-bin/request/asos.py? station=DEN&data=sknt&year1=2016&month1=6&day1=1&year2= 2016&month2=6&day2=30&tz=America%2FDenver&format=comma& latlon=no&direct=no&report_type=1&report_type=2

When you are making an HTTP request using the GET or POST functions from the httr package, you can include the key-value pairs for any query parameters as a list object in the query argument of the function.

```
library(httr)
meso url <- paste0("https://mesonet.agron.iastate.edu/",
                   "cgi-bin/request/asos.py/")
denver <- GET(url = meso_url,</pre>
              query = list(station = "DEN", data = "sped",
                            vear1 = "2016", month1 = "6",
                            day1 = "1", year2 = "2016",
                            month2 = "6", day2 = "30",
                            tz = "America/Denver",
                            format = "comma"))
```

You can then use content from httr to retrieve the contents of the HTTP request. For this particular web data, the requested data is a comma-separated file, so you can convert it to a dataframe with read_csv:

```
denver %>% content() %>%
  readr::read_csv(skip = 5, na = "M") %>%
  slice(1:3)
```

Example R API wrappers

rOpenSci

rOpenSci (https://ropensci.org):

"At rOpenSci we are creating packages that allow access to data repositories through the R statistical programming environment that is already a familiar part of the workflow of many scientists. Our tools not only facilitate drawing data into an environment where it can readily be manipulated, but also one in which those analyses and methods can be easily shared, replicated, and extended by other researchers."

rOpenSci

rOpenSci collects a number of packages for tapping into open data for research: https://ropensci.org/packages

Some examples (all descriptions from rOpenSci):

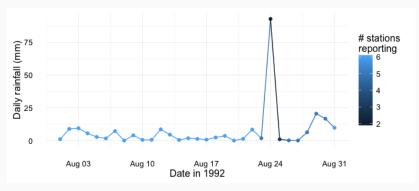

- AntWeb: Access data from the world's largest ant database
- chromer: Interact with the chromosome counts database (CCDB)
- gender: Encodes gender based on names and dates of birth
- musemeta: R Client for Scraping Museum Metadata, including The Metropolitan Museum of Art, the Canadian Science & Technology Museum Corporation, the National Gallery of Art, and the Getty Museum, and more to come.
- rusda: Interface to some USDA databases
- webchem: Retrieve chemical information from many sources.
 Currently includes: Chemical Identifier Resolver, ChemSpider,
 PubChem, and Chemical Translation Service.

"Access climate data from NOAA, including temperature and precipitation, as well as sea ice cover data, and extreme weather events"

- Buoy data from the National Buoy Data Center
- Historical Observing Metadata Repository (HOMR))— climate station metadata
- National Climatic Data Center weather station data
- Sea ice data
- International Best Track Archive for Climate Stewardship (IBTrACS)— tropical cyclone tracking data
- Severe Weather Data Inventory (SWDI)

countyweather

The countyweather package wraps the rnoaa package to let you pull and aggregate weather at the county level in the U.S. For example, you can pull all data from Miami during Hurricane Andrew:

countyweather

When you pull the data for a county, the package also maps the contributing weather stations:

- HIALEAH, FL US
- MIAMI BEACH, FL US
- MIAMI INTERNATIONAL AIRPORT, FL US
- TAMIAMI TRAIL 40 MI. BEND, FL US
- MIAMI WEATHER SERVICE OFFICE CITY, FL US
- PERRINE 4 W, FL US

USGS-R Packages

USGS has a very nice collection of R packages that wrap USGS open data APIs: https://owi.usgs.gov/R/

"USGS-R is a community of support for users of the R scientific programming language. USGS-R resources include R training materials, R tools for the retrieval and analysis of USGS data, and support for a growing group of USGS-R developers."

USGS R Packages

USGS R packages include:

- dataRetrieval: Obtain water quality sample data, streamflow data, and metadata directly from either the USGS or EPA
- EGRET: Analysis of long-term changes in water quality and streamflow, including the water-quality method Weighted Regressions on Time, Discharge, and Season (WRTDS)
- laketemps: Lake temperature data package for Global Lake Temperature Collaboration Project
- lakeattributes: Common useful lake attribute data
- soilmoisturetools: Tools for soil moisture data retrieval and visualization

US Census packages

A number of R packages help you access and use data from the U.S. Census:

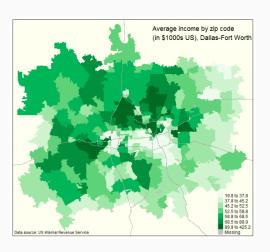

- tigris: Download and use Census TIGER/Line shapefiles in R
- acs: Download, manipulate, and present American Community
 Survey and Decennial data from the US Census
- USABoundaries: Historical and contemporary boundaries of the United States of America
- idbr: R interface to the US Census Bureau International Data Base API

tigris package

- Location boundaries
 - States
 - Counties
 - Blocks
 - Tracks
 - School districts
 - Congressional districts
- Roads
 - Primary roads
 - Primary and secondary roads
- Water
 - Area-water
 - Linear-water
 - Coastline
- Other
 - Landmarks
 - Military

tigris package

Example from: Kyle Walker. 2016. "tigris: An R Package to Access and Work with Geographic Data from the US Census Bureau". The R Journal.

Other R API wrappers

Here are some examples of other R packages that faciliate use of an API for open data:

- twitteR: Twitter
- Quand1: Quandl (financial data)
- RGoogleAnalytics: Google Analytics
- WDI, wbstats: World Bank
- GuardianR, rdian: The Guardian Media Group
- blsAPI: Bureau of Labor Statistics
- rtimes: New York Times

R and APIs

Find out more about writing API packages with this vignette for the httr package: https://cran.r-project.org/web/packages/httr/vignettes/api-packages.html.

This document includes advice on error handling within R code that accesses data through an open API.

Parsing webpages

Parsing webpages

You can also use R to pull and clean web-based data that is not accessible through a web API or as an online flat file.

In this case, the strategy is:

- Pull in the full web page file (often in HTML or XML)
- Parse or clean the file within R (e.g., with regular expressions)

library(rvest)

The rvest package should be the first thing you try if you need to pull and parse data from a webpage that is not a flat file.

This package allows you to read an HTML or XML file and pull out a certain element. Here is a very simple example of this parsing (this and later examples are from rvest documentation):

```
read_html("<html><title>Hi<title></html>")

## {xml_document}

## <html>
## {html>
## [1] <head>\n<meta http-equiv="Content-Type" content="text/htm")</pre>
```

If you have an HTML or XML page you want to pull data from, you'll first need to read the page:

```
library(rvest)
lego_movie <- read_html("http://www.imdb.com/title/tt1490017/")</pre>
lego movie
## {xml_document}
## <html xmlns:og="http://ogp.me/ns#" xmlns:fb="http://www.faceb
```

[1] <head>\n<meta http-equiv="Content-Type" content="text/htm ## [2] <body id="styleguide-v2" class="fixed">\n<script>\n

if

[1] 7.8

Then you can use html_nodes and html_text to pull and parse just the elements you want:

```
rating_node <- lego_movie %>% html_nodes("strong span")
rating_node
## {xml nodeset (1)}
## [1] <span itemprop="ratingValue">7.8</span>
rating <- rating node %>%
   html text() %>% as.numeric()
rating
```

88

You can pull and parse tables:

```
lego_movie %>%
html_nodes("table") %>% `[[`(1) %>%
html_table() %>% select(X2) %>% slice(2:8)
```

```
## # A tibble: 7 x 1
##
                 X2
##
              <chr>
## 1
        Will Arnett
## 2 Elizabeth Banks
## 3
        Craig Berry
## 4
        Alison Brie
## 5 David Burrows
## 6 Anthony Daniels
## 7
        Charlie Day
```

The only tricky part of this is figuring out which CSS selector you can use to pull a specific element of a webpage.

You can use "Selectorgadget" to help with this. Read the vignette for that tool here: ftp://cran.r-project.org/pub/R/web/packages/rvest/vignettes/selectorgadget.html

```
cities <- c("denver", "boulder", "fort-collins")</pre>
kitchen addresses <- c()
for(i in 1:length(cities)){
  restaurant_url <- paste0("http://thekitchen.com/the-kitchen-",
                            cities[i])
  restaurant page <- read html(restaurant url)
  address <- restaurant_page %>%
    html nodes("p:nth-child(2)") %>% html text()
  kitchen addresses[i] <- address[1]</pre>
kitchen addresses
```

```
library(ggmap)
library(stringr)
kitchen_latlons <- geocode(kitchen_addresses)</pre>
```

```
for(i in 1:length(cities)){
  city_map <- get_map(paste(gsub("-", " ", cities[i]),</pre>
                             "colorado").
                      zoom = 14,
                      maptype = "roadmap")
  city map <- ggmap(city map) +
    geom_point(data = kitchen_latlons[i, ],
               aes(x = lon, y = lat),
               color = "red", size = 4, alpha = 0.4) +
    theme void() +
    ggtitle(paste("The Kitchen in",
                  str_to_title(gsub("-", " ", cities[i]))))
  print(city_map)
```
